- Computational methods for Bayesian Inference

# Our researcher and research topic

Researcher: Dr Kostas Kalogeropoulos

- ▶ Computational methods for Bayesian Inference

Research topic: Epidemic Modelling

- ▶ Transmission dynamics of disease
- ▶ Predict potential outbreaks
- ▶ Assess effectiveness of public health interventions

## Overview: Malesios et al. (2017)

Bayesian epidemic models for spatially aggregated count data. C. Malesios, N. Demiris, K. Kalogeropoulos, and I. Ntzoufras. 2017.

- ▶ Problem tackled: To address the spatial nature of the disease spread
- ▶ Measures: Bayesian modelling, branching process-based methods

## Overview: Dureau et al. (2016)

A Bayesian approach to estimate changes in condom use from limited human immunodeficiency virus prevalence data. J. Dureau, K. Kalogeropoulos, P. Vickerman, M. Pickles, M. Boily. 2016.

- ▶ Aim: to estimate condom use time trends from HIV prevalence data to assess the effectiveness of public health interventions
- ▶ Problem tackled: bias, limited self-reported data
- ▶ Measures: a Bayesian inference methodology that incorporates an HIV transmission dynamics model

## Overview: Dureau et al. (2013)

Capturing the time-varying drivers of an epidemic using stochastic dynamical systems. J. Dureau, K. Kalogeropoulos, M. Baguelin. 2013.

- ▶ The methodology illustrated on data from A/H1N1 (2009) pandemic in England
- ▶ A flexible modelling framework encompassing time-varying aspects of the epidemic

## Conclusion

Coronavirus

# Methodology: SEIR

The **SEIR** model divides the population into four groups:

- ▶ **Susceptible**
- ▶ **Exposed** (infected but not infective)
- ▶ **Infective**
- ▶ **Removed** (immune or recovered)

$$\frac{dS_t}{dt} = -\beta S_t \frac{I_t}{N}, \quad \frac{dE_t}{dt} = -\beta S_t \frac{I_t}{N} - kE_t, \quad \frac{dI_t}{dt} = kE_t - \gamma I_t, \quad \frac{dR_t}{dt} = \gamma I_t$$

Assumption: all individual characteristics are fixed over time

Reaction	Effect	Rate
infections	$(S_t, E_t, I_t, R_t) \rightarrow (S_t - 1, E_t + 1, I_t, R_t)$	$\beta_t I_t / N$
onset of symptoms	$(S_t, E_t, I_t, R_t) \rightarrow (S_t, E_t - 1, I_t + 1, R_t)$	$k$
recovery	$(S_t, E_t, I_t, R_t) \rightarrow (S_t, E_t, I_t - 1, R_t + 1)$	$\gamma$

$\beta$  is the effective contact rate which directly reflects transmissibility

## Methodology: suitability of the model

Time-varying factors: behaviour changes, preventive measures, seasonal effects, holidays

## Methodology: adding randomness

Introduce randomness in the parameters (Bayesian) and model  $\beta$  as a probability distribution. Assumption: population model, the random individual effects (biological factors, mode and frequency of travel) are aggregated in the data and hence captured in  $\beta_t$ .

$$\begin{cases} \frac{dS_t}{dt} = -\beta_t S_t \frac{I_t}{N}, \quad \frac{dE_t}{dt} = -\beta_t S_t \frac{I_t}{N} - kE_t, \quad \frac{dI_t}{dt} = kE_t - \gamma I_t, \quad \frac{dR_t}{dt} = \gamma I_t \\ dx_t = \mu_x(x_t, \theta_x)dt + \sigma_x(x_t, \theta_x)dB_t, \quad x_t = h(\beta_t) \end{cases}$$

Add diffusion process  $x_t$  for  $\beta_t$  which will solve the stochastic differential equations in our model.

$$\pi(x_{0:n}|y_{1:n}) \propto f(y_{1:n}|V_{0:n}, \theta_y) \times d\mathbb{P}_x \times \pi(\theta)$$

Sample the posterior of  $x$  given the priors using a specific Markov Chain Monte Carlo (MCMC) type algorithm.

# Motivation for Markov Chain Monte Carlo (MCMC)

- ▶ Intractable integrals  $\rightarrow$  approximate by sampling (Monte Carlo)
- ▶ No closed form of the density to sample from (by e.g. reverse integral transform)  $\rightarrow$  use Markov chains
- ▶ A general name for algorithms based on this is Markov Chain Monte Carlo (MCMC)

## Metropolis-Hastings (random walk Metropolis) example

```
mh <- function(target, starting, N) {  
  x <- rep(0, N)  
  x[1] <- starting  
  for(i in 2:N) {  
    last <- x[i-1]  
    # Proposal from N(last, 1)  
    p <- rnorm(1, mean=last, sd=1)  
    # Compute acceptance probability  
    accept <- target(p) / target(last)  
    # Either with acceptance probability  
    if(runif(1) < accept) {  
      x[i] <- p  
    } else {  
      x[i] <- last  
    }  
  }  
  return(x)  
}
```

# Challenges of MCMC

- ▶ Mixing – relates to dependency of samples obtained with MCMC algorithm and how fast we can get them, can be assessed by Estimated Sample Size (ESS)
- ▶ Let  $x_t = h(\beta_t)$  where  $h$  is a positive-valued function, authors use natural log
- ▶ We want to obtain joint posterior density  $p(x, \theta | y)$  – this is a non-standard problem since
  - ▶ The  $x$  is high-dimensional (it's the path of  $\beta$ )
  - ▶ There is some dependence between  $x$  and  $\theta$
  - ▶ In effect, classic methods are highly inefficient in mixing

## Solution proposed by authors

- ▶ Particle filters (PF) and Particle MCMC (PMCMC)
  - ▶ PF gives us  $p(x | y, \theta)$  and  $p(y | \theta)$  (Doucet and Johansen, 2009)
  - ▶ PMCMC gives us  $p(x, \theta | y)$  (Andrieu et al., 2010)
- ▶ There are still some issues with efficiency
- ▶ Adaptive Metropolis (Roberts and Rosenthal, 2009)
- ▶ Other methods such as Extended Kalman Filter (EKF) are considered but they require some assumptions which would constrain the generality of the proposed solution

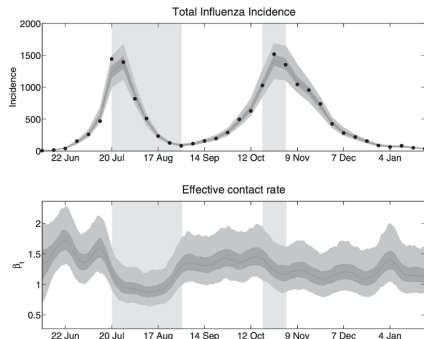

# Results: effect of school closures

- ▶ Black dots indicate estimates of observed incidence
- ▶ Grey rectangular areas indicate school breaks
- ▶ Dark and light area indicates the credible intervals
- ▶ Offline estimates of the effective contact rate

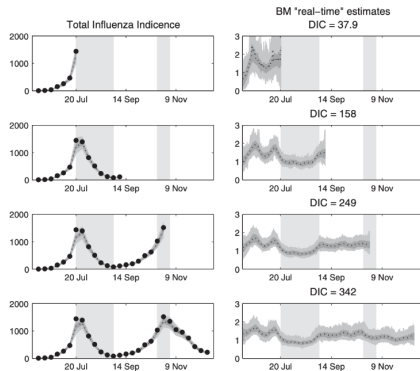

# Results: effect of school closures

- ▶ Holidays periods have shown less total incidences.
- ▶ This could also mean that the epidemic had stopped because a critical population already had been infected, conferring that there is groups that have the immunity to stop the epidemic.
- ▶ The rise in influenza in the second grey area could contribute to the fact that schools were reopened and consequently effective contact rate increased them again.

# Results: relationship between influenza cases and the real-time estimates

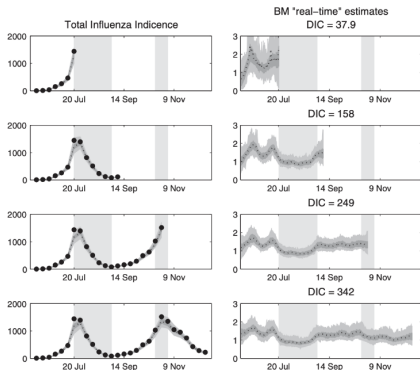

- ▶ Rise of H1N1 incidence fell throughout the school holidays and started rising again.
- ▶ An assumption could be made that decision-makers did not have access to the effective contact rate estimates data.
- ▶ From the data, it could be seen that the real-time estimates were still rising at the first grey area.
- ▶ Reopening schools while the effective contact rate was still rising contributed to another rise in total incidence.

# Results: relationship between influenza cases and the real-time estimates

Some things to consider

- ▶ The effects of school holidays differ from children and adults
- ▶ We assumed here a homogeneous population.
- ▶ Will be more precise to consider a model with two age groups

# Evolution of the subject

- ▶ SSM: Inference for time series analysis with State Space Models. Dureau et al. 2013.
- ▶ Optimal control and the value of information for a stochastic epidemiological SIS-model. Grandits et al. 2019.
- ▶ Efficient real-time monitoring of an emerging influenza pandemic: how feasible? Birrell et al. 2019.

# Outline

## Introduction

- Evolution

## Conclusion

- Coronavirus

# Conclusion: current coronavirus cases in China

## Conclusion: general remarks and questions

Bayesian Inference is a powerful tool, applicable to a vast range of problems. If you like the subject, consider taking ST308, a course on Bayesian Inference lectured by Dr Kalogeropoulos.

We're now happy to take any questions.
